# Dealing with Images

- Each pixel is one input neuron
- Image is 128 px \* 128 px size (Gray scale image)
  - Input number of neurons:  $128 * 128 = 16,384$
- Consider a color image (3 Channels):
  - Input number of neurons:  $128 * 128 * 3 = 49,152$

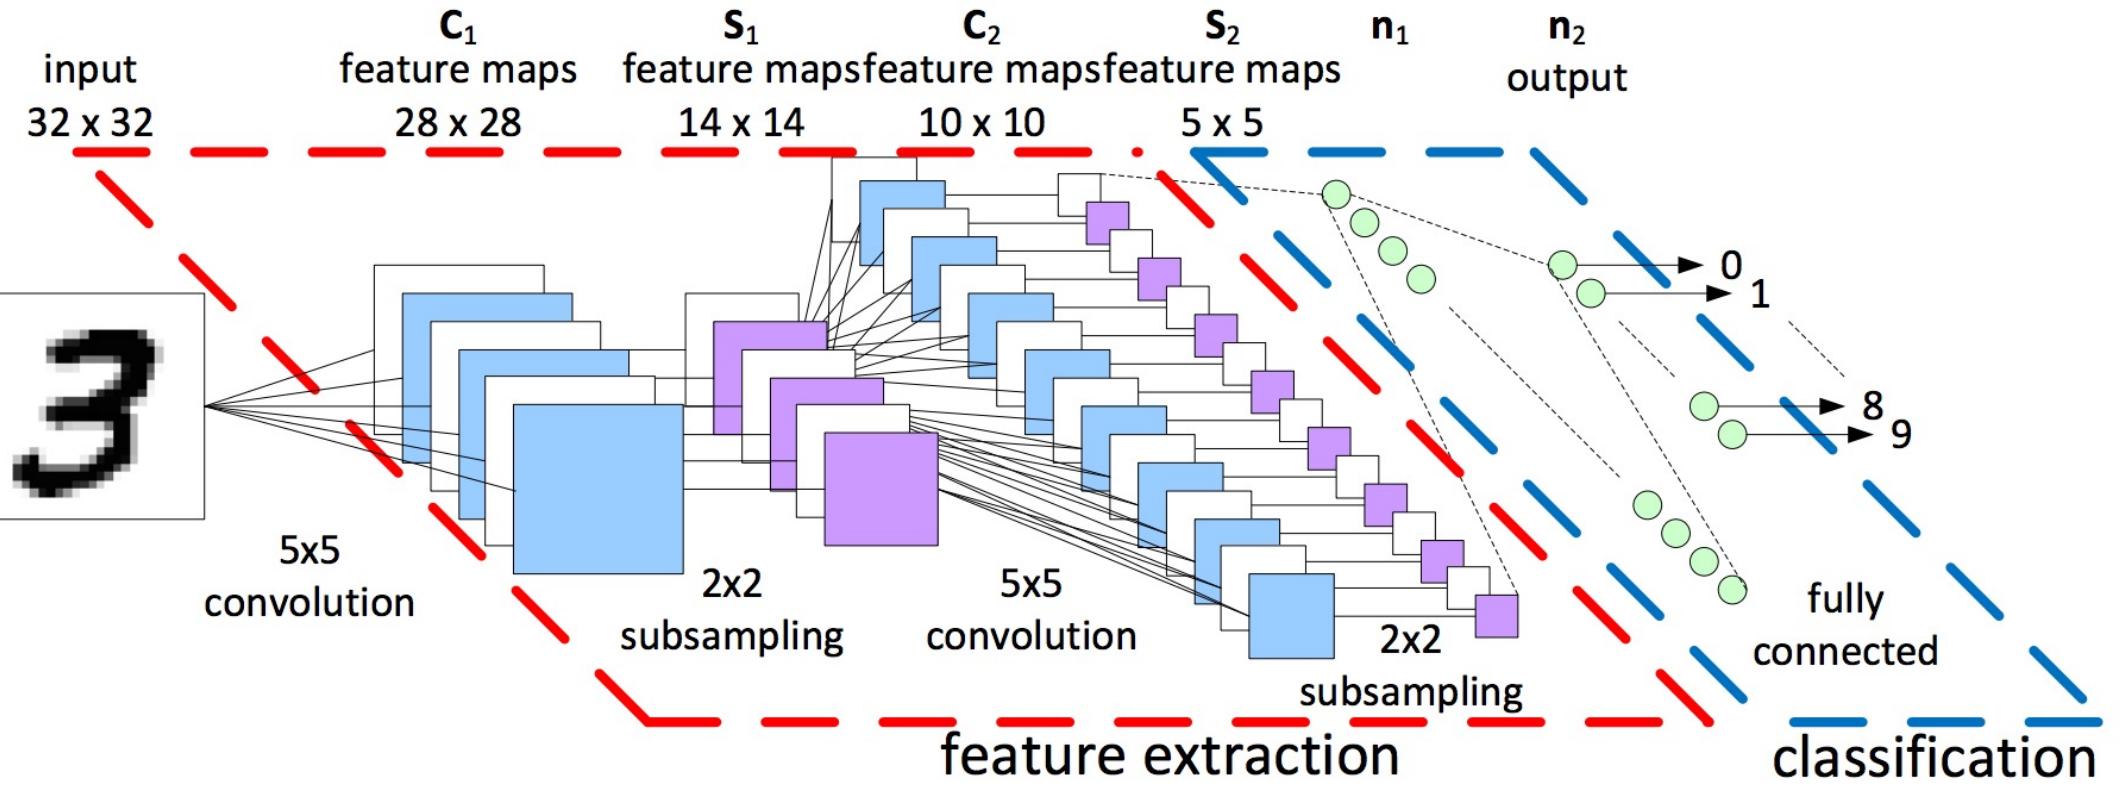

# Dealing with Images

- Each pixel is one input neuron
- Image is 128 px \* 128 px size (Gray scale image)
  - Input number of neurons:  $128 * 128 = 16,384$
- Consider a color image (3 Channels):
  - Input number of neurons:  $128 * 128 * 3 = 49,152$
- Work with larger images:
  - Image size is  $1000 * 1000 * 3 = 3000000 = 3$  million input neurons
  - Complexity: if 1000 hidden neurons then, Number of weights =  $3$  million \* 1000
  - Weight Matrix =  $3$  million \* 1000 = 3 billion parameters

# Dealing with Images

Drawbacks of processing large images:

- Memory requirements will be higher
- Dataset requirement will be higher to train such a neural network.

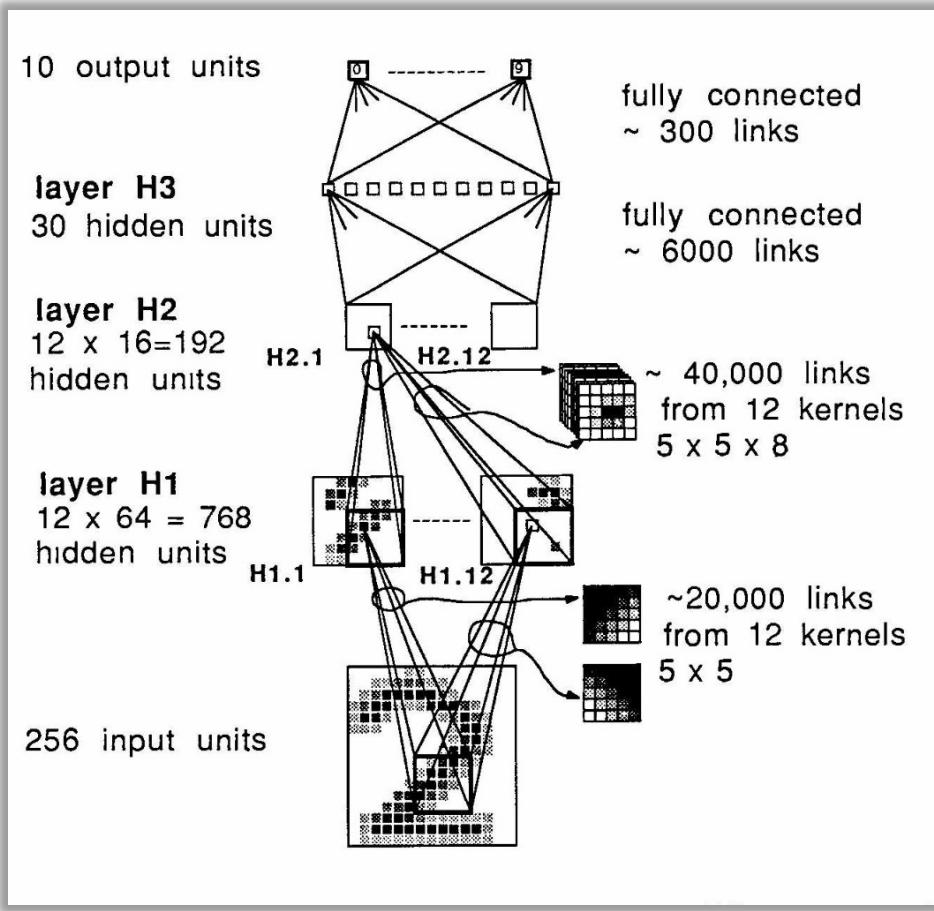

# Convolutional Neural Network

# What is Convolutional Neural Network?

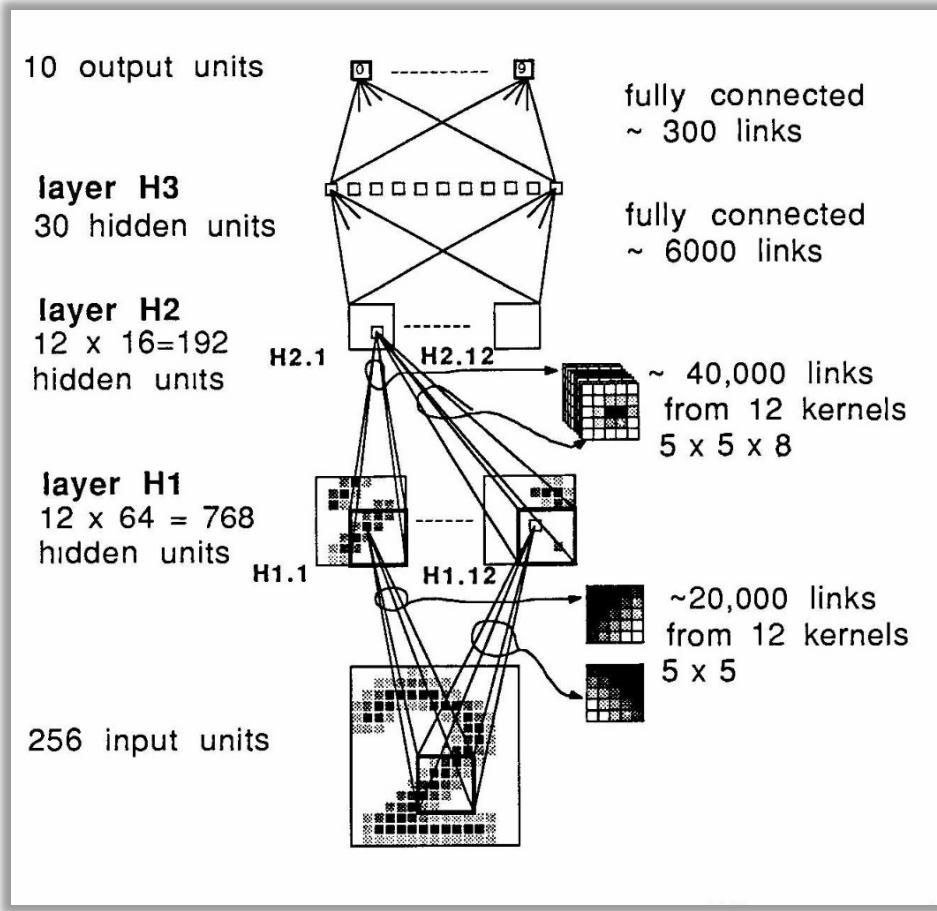

**Convolution** is a mathematical operation on two functions that produces a third function.

$$f(x)*g(x)=t(x)$$

- Pooling or Sub sampling
- Flatenning
- Non-Linearity (ReLU, Tanh)
- Classification or Fully Connected Layer

# Convolution step

- Purpose of Convolution is to extract significant features from the input image
- Learns small features from the input data.

$$\begin{array}{l} A = \begin{matrix} 1 & 1 & 1 & 0 & 0 \\ 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 \end{matrix} * \begin{matrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 1 \end{matrix} = \begin{matrix} 1_{x1} & 1_{x0} & 1_{x1} & 0 & 0 \\ 0_{x0} & 1_{x1} & 1_{x0} & 1 & 0 \\ 0_{x1} & 0_{x0} & 1_{x1} & 1 & 1 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 \end{matrix} = \begin{matrix} 4 & & \\ & & \\ & & \\ & & \\ & & \end{matrix} \end{array}$$

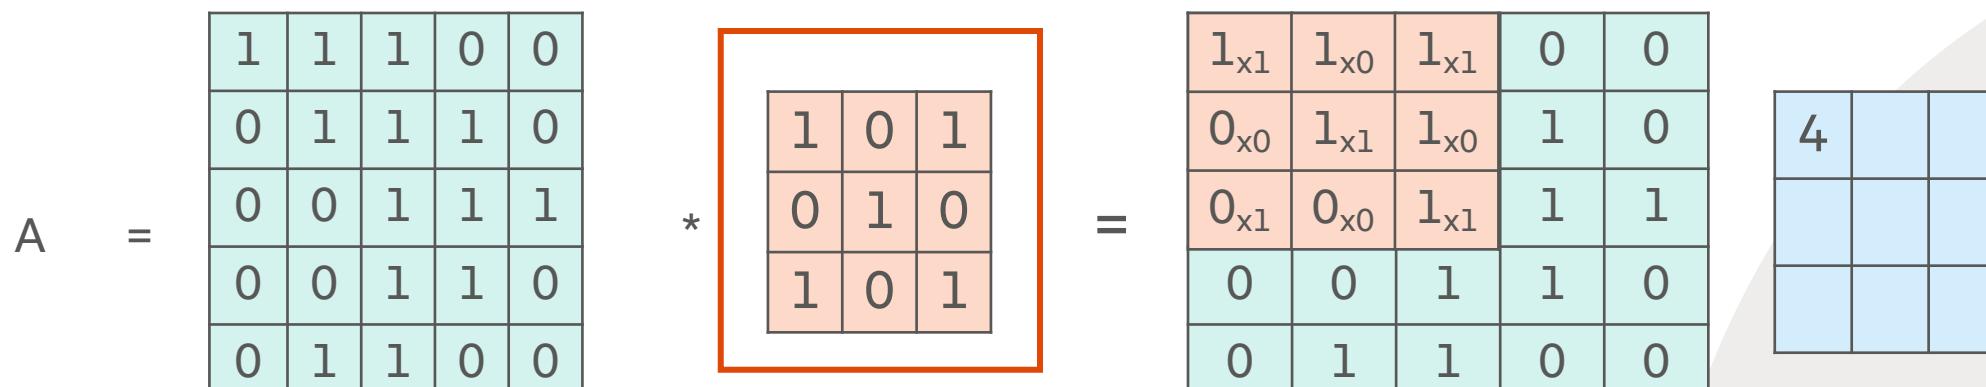

Input image                  Filter/Kernel /Feature Detector                  Convolved Feature/Activation Map/Feature Map

# Filters

- Filters is the matrix with the random values that help to extract feature from the image.
- Different size of filters can be used based on input image.

$$A = \begin{bmatrix} 1 & 1 & 1 & 0 & 0 \\ 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 \end{bmatrix} * \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 1_{x1} & 1_{x0} & 1_{x1} & 0 & 0 \\ 0_{x0} & 1_{x1} & 1_{x0} & 1 & 0 \\ 0_{x1} & 0_{x0} & 1_{x1} & 1 & 1 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 \end{bmatrix}$$

Input image                  Filter/Kernel /Feature Detector                  Convolved Feature/Activation Map/Feature Map

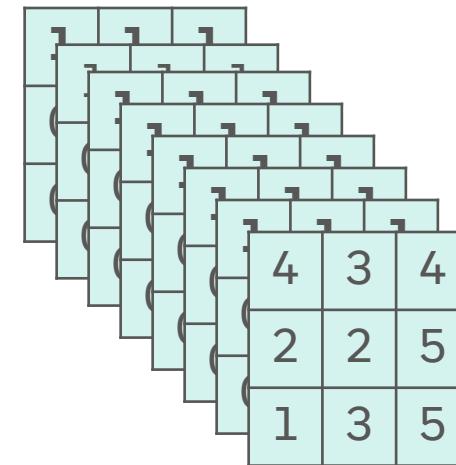

# Filters

- Number of filters is an important parameter in the convolution layer.
- Considering a random number of 8 filters with filter size 3\*3.
- Thus, number of weights =  $3 \times 3$  (Filter size) \* 8 (number of filters) = 72 weights

1	1	1	0	0
0	1	1	1	0
0	0	1	1	1
0	0	1	1	0
0	1	1	0	0

# Convolution step

- A generic formula can be considered:

$$[N \times N] * [f \times f] = [(N-f+1) \times (N-f+1)]$$

Where,  $[N \times N]$  is the input image matrix dimension and  $[f \times f]$  is the matrix dimension for the convolving filter.

# Convolution step

## Drawback 1:

- Drawback of convolving operation is that the Input Image dimension shrinks as there is reduction in the output matrix dimension.

Example:  $[5 \times 5]$  got reduced to  $[3 \times 3]$

- At the end of the neural network it might shrink to  $[1 \times 1]$
- **Image Shrinking is the important drawback**

# Convolution step

## Drawback 1:

- Drawback of convolving operation is that the Input Image dimension shrinks as there is reduction in the output matrix dimension.

Example:  $[5 \times 5]$  got reduced to  $[3 \times 3]$

- At the end of the neural network it might shrink to  $[1 \times 1]$
- **Image Shrinking is the important drawback**
- **Ideal scenario:** Image Shrinking does not take place for every detection of edges or features.

# Convolution step

## Drawback 2:

- Pixel at the corners of the image is used only once.

# Padding

- Shrinking output image and Pixel importance at the edge is overcome using **Padding**.

1	1	1	0	0
0	1	1	1	0
0	0	1	1	1
0	0	1	1	0
0	1	1	0	0

# Padding

- Shrinking output image and Pixel importance at the edge is overcome using **Padding**.

1	1	1	0	0
0	1	1	1	0
0	0	1	1	1
0	0	1	1	0
0	1	1	0	0

0	0	0	0	0	0	0
0	1	1	1	0	0	0
0	0	1	1	1	0	0
0	0	0	1	1	1	0
0	0	0	1	1	0	0
0	0	1	1	0	0	0
0	0	0	0	0	0	0

# Padding

- As an output we can get the original image size.

$$[N \times N] * [f \times f] = [(N-f+1) \times (N-f+1)]$$

Input image  $[5 \times 5]$  padded with one pixel is converted into  $[7 \times 7]$  matrix

- Output matrix  $= [(7 - 3 + 1) \times (7 - 3 + 1)] = [5 \times 5]$
- The equation when padding is added is modified as follows:

$$[(N+2p) \times (N+2p)] * [f \times f] = [(N+2p-f+1) \times (N+2p-f+1)]$$

Where,  $N$  is the input image dimension,  $p$  is the padding pixel value, and  $f$  is the filter matrix dimension.

# Valid Convolution / Same Convolution

# Valid Convolution / Same Convolution

## — Valid Convolution

$$[N \times N] * [f \times f] = [(N-f+1) \times (N-f+1)]$$

## — Same Convolution: Padding is involved so that output size is the size as the input size.

$$[(N+2p) \times (N+2p)] * [f \times f] = [(N+2p-f+1) \times (N+2p-f+1)]$$

# Valid Convolution / Same Convolution

**What is the ideal value of Padding pixel?**

# Valid Convolution / Same Convolution

**What is the ideal value of Padding pixel?**

— Solution:

$$(N+2p-f+1)=N$$

$$p = ((f-1))/2$$

Therefore, filter size value ( $f$ ) is always **ODD** number.

Because  $f$  is **EVEN** then asymmetric padding, then **NO** central position in the image matrix.

# Strided Convolution

- Combining all the concepts learnt till now:
- If the input image is  $[N \times N]$  and filter size is  $[f \times f]$ , where  $p$  is the padding pixel value and  $s$  is the stride value then the final equation looks like:

$$[(N+2p) \times (N+2p)] * [f \times f] = [((N+2p-f)/s)+1) \times ((N+2p-f)/s)+1)]$$

- If the stride makes the filter goes outside, then the computation is not taken place.

# Convolution on RGB Images

- [ $5 \times 5 \times 3$ ] => 5 is the height and width and 3 are the number of channels (RGB)

# Convolution on RGB Images

- [5 x 5 x 3] \* [3 x 3 x 3] => 3 is the height and width and 3 are the number of channels (RGB)

# How Convolutional Neural Network Work?

- Convolution Layer
- **Pooling or Sub sampling**
- Flatenning
- Non-Linearity (ReLU, Tanh)
- Classification or Fully Connected Layer

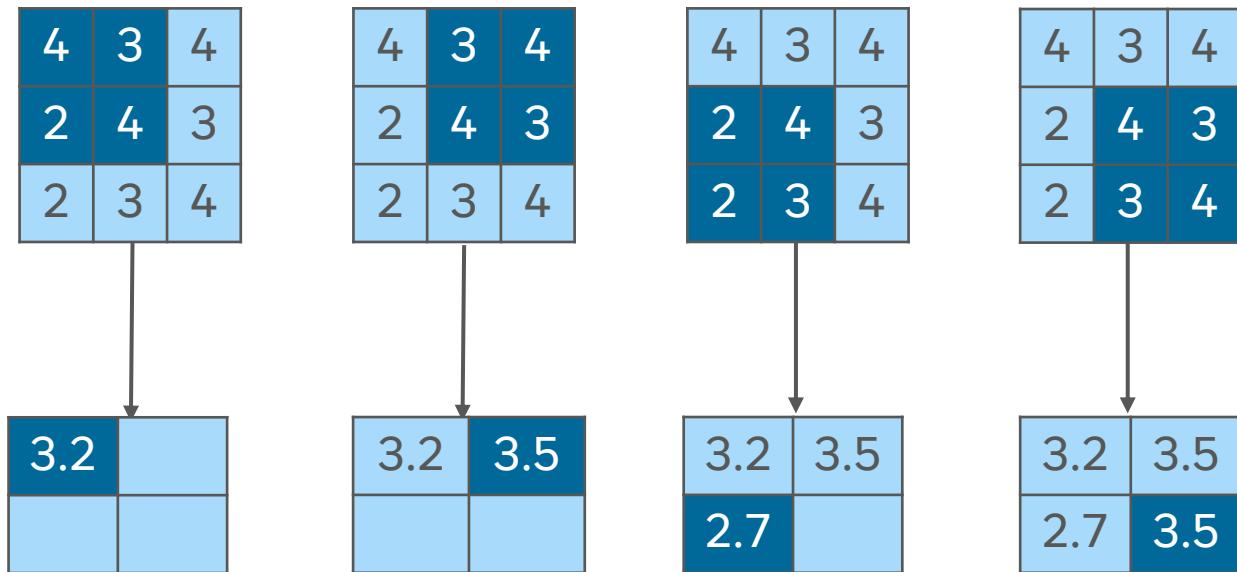

# Pooling (Sub sampling/Down sampling)

- Reduces the dimensionality of the feature map but also retains the most significant information.
- Different types of Pooling techniques based on decided pool size.

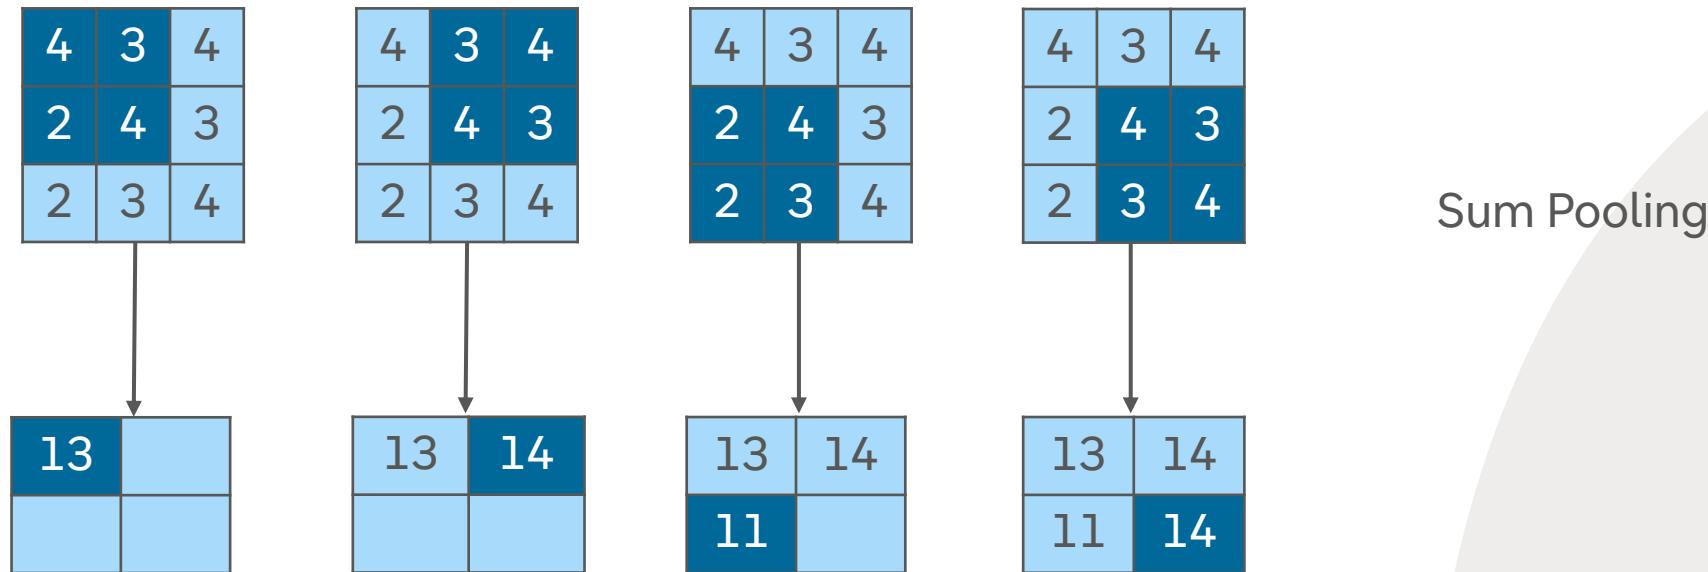

# Pooling (Sub sampling/Down sampling)

- Reduces the dimensionality of the feature map but also retains the most significant information.
- Different types of Pooling techniques based on decided pool size.

# Pooling (Sub sampling/Down sampling)

- Reduces the dimensionality of the feature map but also retains the most significant information.
- Different types of Pooling techniques based on decided pool size.

# Pooling (Sub sampling/Down sampling)

- Most popular is **Max Pooling**.
- Advantages of Pooling is to makes the input representations (Feature dimension) smaller and more manageable.
- Reduces the number of parameters and computations in the network, therefore controlling overfitting.

# How Convolutional Neural Network Work?

- Convolution Layer
- Pooling or Sub sampling
- **Flattening**
- Non-Linearity (ReLU, Tanh)
- Classification or Fully Connected Layer

# Flattening

- After the convolution and pooling is performed, a final matrix is obtained.
- The obtained matrix can now be passed to the Fully connected layer for the classification purpose.
- As matrix cannot be passed directly to the Fully connected layer, Flattening is performed.
- Flatten is the concept of converting the matrix into a 1-D array value.

# How Convolutional Neural Network Work?

- Convolution Layer
- Pooling or Sub sampling
- Flattening
- **Non-Linearity (ReLU, Tanh)**
- Classification or Fully Connected Layer

# Non-linearity (ReLU)

- Rectified Linear Unit (Non-linear operation)
- Element wise operation
- Non-linearity in the neural network
- Convolution is a linear operation.

$$f[x, y] * g[x, y] = \sum_{n_1=-\infty}^{\infty} \sum_{n_2=-\infty}^{\infty} f[n_1, n_2] * g[x - n_1, y - n_2]$$

# How Convolutional Neural Network Work?

- Convolution Layer
- Pooling or Sub sampling
- Flattening
- Non-Linearity (ReLU, Tanh)
- **Classification or Fully Connected Layer**

# Fully Connected Layer

- Multi Layer Perceptron is used as fully connected layer, SoftMax function at output layer
- Fully connected layer means every neuron from one layer is connected to each neuron of another layer.
- The output from convolution and pooling represent the high level feature of the input image.

# Fully Connected Layer

- Fully connected layer uses these features in order to perform classification into various classes based on training dataset.
- Dropout is the process of dropping out some neurons from the neural networks during the training process. This dropout prevents the neural network from overfitting.

# Convolutional Neural Network

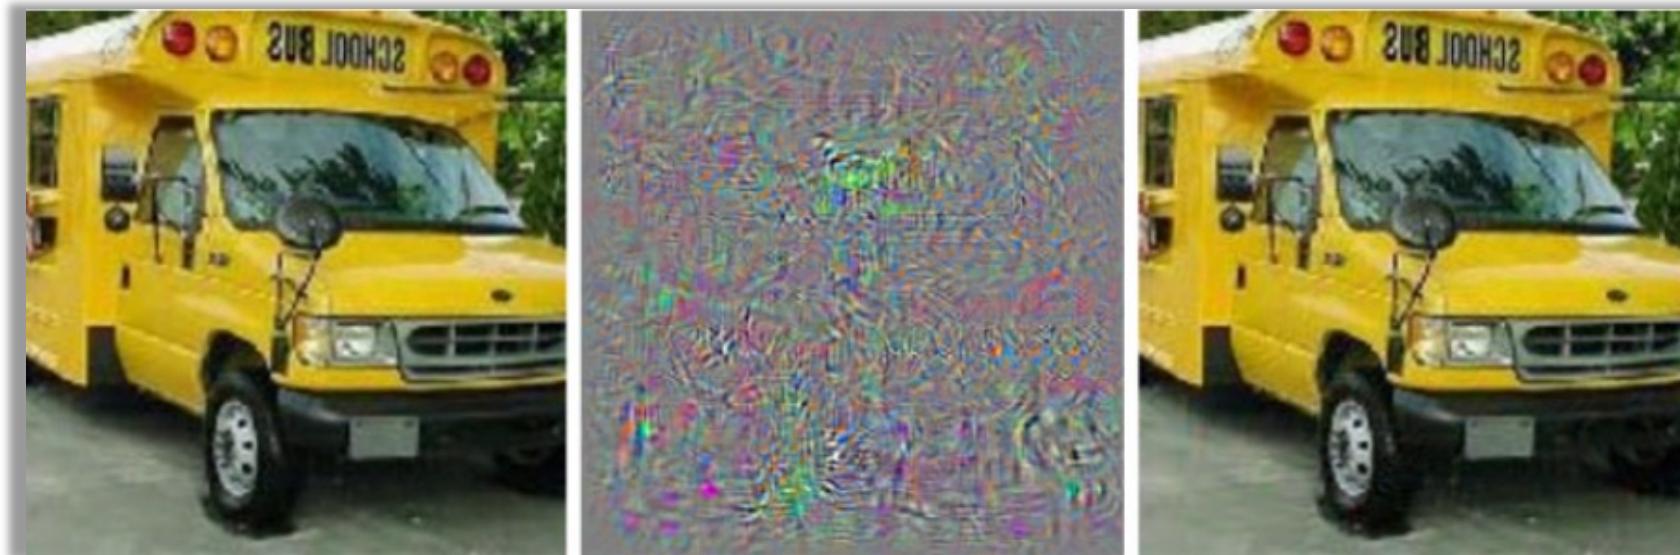

- Convolution and Pooling layer helps to identifying features from the image.  
(Feature Learning)
- Fully connected layer considers these features to classify into different categories.  
(Classification)
- Training dataset is large then Neural network will learn and generalize well to new images.

# Hyper-Parameters of CNN

- Input Size
- Padding
- Kernel Size
- Stride
- Number of filters or Kernel

# Drawbacks of Convolutional neural network

- As CNN are supervised learning method, require a large set of label data for training.
- CNN can be defeated by carefully adding a crafted noise into the image.
